Abstract

Every power consumer deserves a good and regular power supply from his service provider, and the quality of service depends on the degree of reliability of the power distribution system. The key factors that determine the reliability of the system are the frequency and duration of fault in the system. Therefore, this research seek to ascertain the level of reliability of electric power distribution network, using the GRA 33/11kVfeeder as case study for the year 2017. This research is unique because it took into consideration the estimated hours of scheduled load shedding in the distribution network. The feeder radiates Dumez, Ihama, Reservation, Oba Palace and GRA 11kV feeders in the network of Benin Electricity Distribution Company (BEDC). A monthly record of both scheduled (load shedding) and unscheduled frequency of interruption, duration of interruption and number of customers on each 11kV feeder were takenfrom the control room for the year under review. Using the basic mathematical tool, the customer service and basic reliability indices were studied for each month after which an average of each element was used for the analysis. Result showed that duration of interruption has a strong impact on the service customer reliability indices. The entire indices also show that Reservation 11kV feeder was worst hit as it had a failure rate of 0.2001 per hour in the year 2017, it also recorded the highest average fault frequency and duration of 145.83 and 469.47hrs respectively which consequently had direct impact on the entire indices. In comparison with international benchmark of 0.9998 for Average Service Availability Index (ASAI), it was observed that the 11kV feeders under study were grossly unreliable as Ihama feeder with the best reliability recorded 0.4634 as ASAI. With transient fault and failure of system components the major causes of failure, a massive overhaul of power system components and smart grid system should be implemented in the networks.

Keywords: Reliability, 11kV Feeders, SAIDI, SAIFI, Load Shedding, ASAI

1.0 INTRODUCTION

Reliability can be defined as the ability to provide uninterrupted power supply for customers, and any system's reliability is measured on the average customer interruption indices [1]. Devices and systems which are designed to carry out specific functions have the properties of reliability. Reliability of power systems can be reviewed from two perspectives, that is, as adequacy of system and security of system. From the former, adequate facilities are provided to meet customer demands and system requirements. Under this system adequacy, some facilities are required to generate adequate energy, while others are meant to wheel out or distribute the energy produced to customers. This system adequacy has to do with static conditions with no system disturbances. From the former, security of systems is the ability of the system in time of disturbance. Under this sub-concept, there are general or locally centralized disturbances which lead to loss of energy generation and distribution system facilities [2, 3].

Egwaile and Oyedoh

Power system reliability is the probability that the power system will continually carry out its defined function of energy delivery to customers with expected quality of service. Power systems reliability evaluation has an effect on the management of asset of the system [4]. In years past, the distribution session of the power sector attracts less attention as regards reliability study and evaluation as compared to the generation and transmission sessions. This is as a result of the fact that generation and transmission possess more expensive and sensitive power systems and any shortfall can result in grave consequences [5]. The situation of electricity in Nigeria is presently erratic and has a direct consequence on industrial, commercial and residential class of the nation's economy [6]. A good number of the outages or downtime is due to damages caused by weather. Other causes can be accidents by vehicles, failure of equipment, animal contact and human error [7].

1.1 **Reliability analyses:**

Reliability indices are used to evaluate power outages and assess the performance of power systems. The power sector uses this index with an informed method for the collection data and analysis [8]. There exist two approaches applied for the evaluation of reliability of power distribution. And they include simulation method which is based on statistical distributions and a good example is the Monte Carlo method and analytic methods which are based on mathematical models. Usually, reliability index evaluation has to do with an approach that is based on failure modes assessment together with the use of equations. The indices are evaluated by considering the rate of failure, the average outage time and the expected annual outage time [5]

1.2 **Reliability Indices:**

Reliability evaluation of power systems measures the performance of the distribution system [9]. The indices statistically aggregate reliability data for a defined set of loads, customers or components. The indices are average values of a particular reliability characteristic for a complete system, substation territory of substation, operating feeder [5]. The indices of reliability frequently used for evaluation of power systems are: System Average Interruption Frequency Index (SAIFI), System Average Interruption Duration Index (SAIDI), Customer Average Interruption Duration Index (CAIDI), Average Service Availability Index (ASAI), Average Service Unavailability Index (ASUI), etc. Failure rate, annual unavailability, and average outage duration are indices which are affiliated with load points of systems.

System Average Interruption Frequency Index (SAIFI): this index has to do with the number of times the customer experiences interruption within a period of time in an area. It is the ratio of the total number of interruptions to the total number of customers served.

$$SAIFI = \frac{Frequency of outages}{Number of Customers served}$$

System Average Interruption Duration Index (SAIDI): this index is associated with the interruption of average service in the system. It serves the purpose of indicating the duration of an outage when there is continuous interruption which lead to power loss. It is the ratio of the total duration of interruption to the total number of customers served.

| SAIDI = | Total duration in hours |
|---------|----------------------------|
| | Number of customers served |

Customer Average Interruption Duration Index (CAIDI): this index determines the average duration for the restoration of service to customers. To improve CAIDI, reducing the duration of interruption and increasing restoration time can be done. CAIDI is the ratio of the sum of customer interruption duration to that of customer interruptions. It is also the ratio of SAIDI to SAIFI.

$$CAIDI = \frac{Total \ duration \ in \ hours}{Number \ of \ affected \ customers}$$

Average Service Availability Index (ASAI): shows the fraction of time (usually in percentage) in which a customer receives power during the defined reporting period.

$$ASAI = \frac{Customer\ hours\ availability}{Consumer\ hours\ service\ demand}$$

Average Service Unavailability Index (ASUI): this is the opposite of ASAI, it shows the fraction of time in percentage in which a customer experiences power interruption during the reviewed period.

Total hours demanded Frequency time is said to be the random variable in reliability, thus, the exponential function is said to be the most appropriate because the only independent variable it possesses is time. Therefore, an important factor to use this function is that the failure rate (λ) should be constant.

Reliability indices can be categorized as the load point indices of the failure rates mean value. Therefore, the density function is as shown below;

 $f(t) = \lambda e^{-\lambda t}$

Transactions of the Nigerian Association of Mathematical Physics Volume 10, (July and Nov., 2019), 109–118

Trans. Of NAMP

| Hence, the failure rate (λ) is given as; | |
|--|--------------------------------------|
| $\lambda(t) = \frac{f(t)}{1 - f(t)} = \frac{frequency of failure}{number of unit-hours of operation}$ | (6) |
| | |
| Failure rate (λ) is regarded as the time rate of change of the probability of failure. It is | dependent on time and it varies over |
| the life cycle of power system and it is the number of failure per unit time [13]. | |
| Furthermore, the following can be calculated from the highlighted parameters above, | |
| Mean Time Between Failure (MTBF) = $\frac{Total hours of system operation}{Frequency of failure}$ | (7) |
| Frequency of failure | (\prime) |
| Mean Time To Repair (MTTR) = $\frac{Total duration of outage}{Frequency of outage}$ | (8) |
| | |
| From the above, the system availability can be calculated as; | |
| Availability = $\frac{MTBF - MTTR}{MTBF}$ | (9) |
| MTBF | |

The Mean Time between Failures (MTBF) defines the average time which terminates between successive failures of repairable system. The longer this parameter, the more the system is said to be reliable.

Mean Time to Repair (MTTR) is the average time needed to restore a system to its operational state after failure. As a maintainability index, the lower its value the more the system is defined to have a good maintainability [11].

Availability (A) is the probability that the system will be in a good state to perform its required function within a given period.

The indices highlighted above are studied to determine the impact faults or breakdown has on the reliability and efficiency of the Benin Electricity Distribution network under study.

2.0 METHOD

This research appraises the level of reliability of a section of the Benin Electricity Distribution Company (BEDC) network. It takes into consideration fault and scheduled data for twelve months for the year 2017. Due to insufficient power generation and massive energy demand in Nigeria, majority of power distribution companies have put in place rationing modalities to enhance energy management among customers on various feeders. Thus, a daily schedule doutage (popularly known as load shedding) of "3hrs on and 3hrs off" which was largely the practice of the utility company managing the feeder under study was considered for the year 2017. This was considered together with unscheduled outage (fault) in the various 11kV feeders under study. The following steps were taken in carrying out this research.

- i) Data containing the major causes of the fault recorded were collected, it is as shown in Table 1
- ii) Data containing number of customers affected, frequency of interruptions and duration of interruptions record per month for Dumez, GRA, Oba Palace, Reservation and Ihama 11kV feeders were collected as shown in Tables 2, 3, 4, 5 and 6 respectively.
- iii) The customer service reliability indices such as SAIFI, SAIDI, CAIDI, ASAI and ASUI were carried out using Eq.(1), Eq.(2), Eq.(3), Eq.(4) and Eq.(5) respectively.
- iv) Basic reliability indices such as failure rate (λ), MTBF, MTTR and Availability was calculated by applying Eq.(6), Eq.(7), Eq.(8) and Eq.(9) respectively.
- v) Calculated results for both the customer service and basic reliability indices were tabulated as shown in Table 7 through Table 12 for the various feeders. The calculated average of each element customer service reliability indices for the year 2017 were presented in charts as shown in Figure 2 to Figure 6, while the result for basic reliability indices were presented in charts as shown in Figure 10. vi) Analysis of result and recommendation.

2.1 Description of case study feeders and associated data collected

These 11kV feeders are tied to GRA injection substation and Etete injection substation. These two substations are fed from GRA 33kV feeders. From the Etete injection substation of 2X15MVA transformers radiate Ihama 11kV feeder and Dumez 11kV feeder.

From GRA injection substation of 2X15MVA which is also from GRA 33kV feeds the following11kV feeders; Reservation, GRA and Oba Place 11kV feeders.

The Dumez 11kV feeder and Ihama 11kV feeder have total lengths of 8.6km and 16.2km respectively. While Reservation, GRA and Oba Place 11kV feeders have 18.3km, 11.9km and 7.2km respectively.

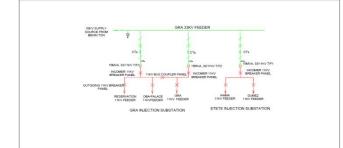

Figure 1: Single Line Diagram showing GRA 33kV Feeder and Associated Injection Substation and 11kV feeder [10]

Reliability Assessment of a...

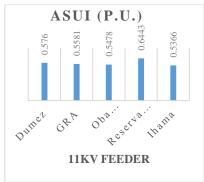

Figure 6: Average Service Unavailability Index per month for the year 2017.

The chartsbelow were gotten from table 12. The values in the table were gotten by taking the average of the total value gotten as the Basic reliability indices for the year 2017.

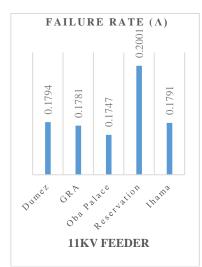

Figure 7: Average Failure rate (λ) per month for the year 2017.

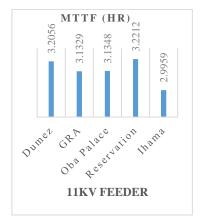

Figure 9: Average Mean Time To Failure (Hr) for the year 2017.

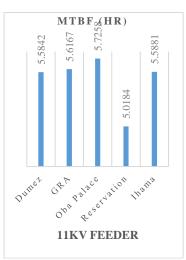

Figure 8: Average Mean Time Between Failure per month for the year 2017.

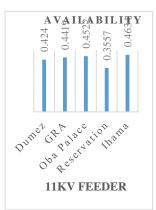

Figure 10: Average Availability for the year 2017

3.2 Discussions

From Table 7 through Table 11 above display the customer service reliability and basic reliability indices of the various 11kV feeders (Dumez, GRA, Oba Palace, Reservation and Ihama) for each month. An average of the total values for each measuring components of each feeder was taken for the year under study, it is as shown in Table 12. From the data for Reservation 11kV feeder table 5 above, it can be seen that Reservation 11kV feeder experienced largest frequency of interruptions with an average value of 145.83 in 2017, and this led to failure rate of 0.2001 per of the same feeder in table 12. While Oba Palace experienced the least number of interruptions and failure rates 127.5 and 0.1747 per hour in table 4 and table 12 respectively.

Figure 2 through figure 6 are the bar charts representing the averages of the various measuring components for the customer service reliability indices for 2017. The charts were produced using the figures in table 12 for the average customer service reliability indices for the various feeders for the year under study. As shown in Figure 2, GRA feeder recorded the highest value of 0.0.3766Hr as the SAIDI, with 0.1084Hr for Reservation which was the least. This is because the SAIDI index considers the duration of interruption as a ratio with the customer population. Relatively, SAIFI was also gotten by considering the customers' population and frequency of interruption and the chart is as shown in Figure 3 with GRA having same value of 0.1201 and Reservation 0.0337. Figure and Figure 6 shows the chart for CAIDI and ASUI where Reservation recorded the highest values of 3.2212 and 0.6443p.u. respectively as expected. In Figure 5, it recorded a corresponding value of 0.3557p.u. as least value for ASAI, indicating the feeder's level of availability.

The bar charts in figure 7, figure 8, figure 9 and figure 10 show the variations of the basic reliability indices. Figure 7 showed that Oba Palace had the least failure rate of 0.1747 while reservation had the most failure rate of 0.2001. Figure 8 shows that the Oba Palace feeder is more reliable as it recorded an average of 5.7258Hr as its MTBF for the year 2017, and again, the Reservation feeder is said to be least reliable with a figure of 5.0184Hr as its average MTBF in 2017. However, Ihama 11kV feeder has best maintainability with a figure of 2.9959Hr as the average MTTR in 2017 as shown in Figure 9. With the failure data the major tool for consideration, Ihama 11kV had the highest value of availability while Reservation 11kV feeder had the least value with values of 0.4634 and 0.3557 respectively. These values of availability appear grossly unimpressive as it implies that even the feeder with the highest availability (also known as ASAI) for Ihama 11kV feeder is way below the international benchmark of 0.9998. This goes to show that a lot needs to be done to revamp the feeder under study and the entire distribution network at large.

From Table 1 above, majority of the unscheduled outage can be ascribed to transient fault and other technical fault such as Jumper/Upriser Cut and Others (Broken Poles, Wire cut, Vehicular Collision, etc.). This goes to show that the components of the power distribution network are obsolete and requires overhauling. There were other causes such as animal bridges and vegetation interference.

CONCLUSION

As indicated in this research, the data collected contains scheduled outages (excluding maintenance) due to load shedding and unscheduled outages due to faults and breakdown in the entire network under study. Following this appraisal on the GRA 33kV network, it can be observed that frequency of interruptions and duration of interruptions have great impact on the assessment. However, timely response to fault interruptions help to improve the system reliability. From the basic reliability and customer service reliability studies, it can be seen that Reservation 11kV feeder is most hit in terms of fault frequencies and duration of faults and the general assessment.

From the overall result on system availability (ASAI), there is great need to improve on the entire network as the achieved results are far below the global benchmark of 0.9998 for ASAI [12]. It is even worse considering the fact that this research only considered scheduled outages (excluding maintenance) due to load shedding and unscheduled.

RECOMMENDATIONS

There is great need to forestall the incessant tripping and downtime of the system and this will relatively improve on the system reliability. The entire system components should be placed on a regular checked for inherent failures and weakness. The minimum requirement for right of way of the power system utilities must be strictly observed by commuters and vehicles. This will reduce collision of vehicles cases. System hardware like wooden poles, crack concrete poles and undersized conductors that are prone to snapping and breakage should be changed from time to time. The entire feeders should be regularly patrolled to cut-off vegetation interfering with power conductors.

Appropriate mechanism of reading and recording fault current in BEDC injection substation should be put in place, as this will aid in network fault analysis and research into BEDC network. In the long term, the use of Supervisory Control and Data Acquisition (SCADA) systems should be integrated into BEDC distribution network operations to allow for real time network data collection. A smart grid system should be implemented.
