# NON-COMMUTATIVE STOPPING TIMES AND TIME PROJECTIONS IN A FILTERED HILBERT SPACE 

A. A. MUHAMMAD and A. A. TIJJANI<br>Department of Mathematics, Ahmadu Bello University, Zaria - Nigeria.

#### Abstract

We present the theory of non-commutative stopping time were the von Neumann algebra is semi-finite that is the von Neumann algebra has a faithful, normal and semi-finite trace. We define a representation mapping and analyze the representation mapping into the existing properties of stopping times and time projection. We also prove the optional stopping theorem.

Keywords: Non-Commutative Stopping Times, Time Projections, Filtered Hilbert Space

## 1. INTRODUCTION

The theory of quantum probability plays a vital role in the study of operator algebras such as $\mathrm{C}^{*}$-algebra, $\mathrm{W}^{*}$-algebra (also known as von Neumann algebra). An operator $T \in B(H)$ (the space of bounded linear operator ( $\mathrm{B}(\mathrm{H})$ ) acting on a Hilbert space $(\mathrm{H})$ ) is a map $B: H \rightarrow H$ which is bounded and linear. A von Neumann algebra is a unital sub-algebra of $B(H)$ which is closed with respect to the weak operator topology.
The theory of von Neumann algebras was initiated and developed by J. von Neumann and F. J. Murray in their series of papers [1-4]. Their theories were extensively studied by many authors such as [5] and [6]. Non-commutative stopping time could trace back to the work of [7] where he formulated the concept of stopping time to a noncommutative setting as a projection valued measure.
The "Stopping non-commutative processes" was investigated by [8] where they indicated that the 'formalism' of stopping times carries over to a non-commutative context exist and prove an Optional Stopping Theorem. Following the ideas of [7], a composition operation in the space of stop time to make it a semigroup was introduced by [9], stop time integrals are also introduced and their properties constitute the basic tools for the subject. They imply the strong Markov property of quantum Brownian motion in the boson as well as fermion sense and the Dynkin-Hunt property that the classical Brownian motion begins afresh at each stop time. The stopped Weyl and fermion processes were defined and their properties were studied. Time Projections in a von Neumann algebra was studied by [10]. In their work they characterized some stopped processes in the theory of stopping times and stopping integration within the context of the Clifford Filtration. The work of [8] was further extended by [11] where they proved an analogue of Doob's optional stopping theorem and in the special case of the quasi-free representation of the Canonical AntiCommutation Relations (CAR) and also proved the random stopping theorem where the underlying von Neumann algebra possesses only a faithful normal state. Random times and their associated time projections within the context of quantum probability theory were discussed by [12]. A stochastic integral representation for time projections was obtained, and their order structure was investigated. Random times, predictable processes and stochastic integration in finite von Neumann algebra were discussed by [13] where they offered a viewpoint for the theory of non-commutative stochastic processes. In support of this view, they considered random times and random stopping as a departure point and constructed a class of predictable processes using random times. They defined various stochastic integrals of these predictable processes and prove some elementary result on a finite von Neumann algebra. Quantum stopping times, quantum stochastic interval, stopping quantum $\mathrm{L}^{1}$-process by quantum stopping times and the relationship between stopping and Doob-Meyer decomposition of the squares of quantum martingales were discussed by [14].

## 2. Preliminaries

In this section, we present preliminary results, definitions and fundamentals of von Neumann algebra.
Definition 2.1 Let H be a separable Hilbert space over the complex field $\mathbb{C}$. The identity operator on H is denoted by $I_{H}$, or $I$ simply if no confusion arises. We introduce the following locally convex topologies in $\mathrm{B}(\mathrm{H})$ :

1. uniform (operator) topology: It is the topology generated by the operator norm $\|$.$\| .$

[^0]2. weak (operator) topology: If a net $a_{i} \rightarrow 0$, then
$\left\langle a_{i} \xi, \eta\right\rangle \rightarrow 0 \forall \xi, \eta \in \mathrm{H}$;
3. strong (operator) topology: If a net $a_{i} \rightarrow 0$, then
$\left\|a_{i} \xi\right\| \rightarrow 0 \forall \xi \in \mathrm{H}$;
4. $\sigma$-weak (operator) topology: If a net $a_{i} \rightarrow 0$, then
$$
\sum_{n}\left\langle a_{i} \xi_{n}, \eta_{n}\right\rangle \rightarrow 0, \forall \sum_{n}\left(\left\|\xi_{n}\right\|^{2}+\left\|\eta_{n}\right\|^{2}\right)<\infty
$$
5. $\sigma$-strong (operator) topology: If a net $a_{i} \rightarrow 0$, then
$\sum_{n}\left\|a_{i} \xi_{n}\right\|^{2} \rightarrow 0 \forall \sum_{n}\left\|\xi_{n}\right\|^{2}<\infty$.
Definition 2.2 A von Neumann algebra $M$ is a unital self-adjoint sub-algebra of $B(H)$ which is closed in the weak operator topology. That is, $\mathrm{I} \in \mathrm{M}, a=a *$ and the net $a_{i} \rightarrow a$ in the weak operator topology if $\left\langle a_{i} \xi, \eta\right\rangle \rightarrow\langle a \xi, \eta\rangle \forall \xi, \eta$ $\in \mathrm{H}$. Alternatively, a * sub-algebra M of $\mathrm{B}(\mathrm{H})$ is called a von Neumann algebra, if $M=M^{\prime \prime}$,
where $M^{\prime \prime}=\{\mathrm{b} \in \mathrm{B}(\mathrm{H}): \mathrm{b} a=a \mathrm{~b}, \forall a \in \mathrm{M}\}$ is the commutant of $M$, and $M^{\prime \prime}=\left(M^{\prime}\right)^{\prime}$ is the double commutant of $M$. Note that $M^{\prime}$ is also a von Neumann algebra.
Definition2.3 Let H be a Hilbert space. A bounded operator P : $\mathrm{H} \rightarrow \mathrm{H}$ is called a projection if
$P^{*}=P^{2}=P$.
Definition 2.4 Let $M$ be a von Neumann algebra and let $w: ~ M \rightarrow k$ be a linear functional on $M$. Then $w$ is said to be i. positive, if $\mathrm{w}(a) \geq 0$ for any $a \in M^{+}$(where $M^{+}=\{a \in M \mid \geq 0\}$ the set of all positive elements of $M$ ), and is denoted by $\mathrm{w} \geq 0$, Moreover, for two linear functionals $\mathrm{w}, \psi$ on $M$, the relation $\psi \leq \mathrm{w}$ means that $(\mathrm{w}-\psi) \geq 0$. A positive linear functional $w$ is said to be:
ii. faithful, if $\mathrm{w}(a)=0$ for some $a \in M^{+}$, then we have $a=0$.
iii. normal, if for any bounded increasing net $\left\{a_{i}\right\} \subset M^{+}$, we have $\sup _{\mathrm{i}} \mathrm{w}(a)=\mathrm{w}\left(\sup _{\mathrm{i}} a\right)$.
iv. state, if $\mathrm{w}(\mathrm{I})=1$.
v. trace, if $\mathrm{w}(a * a)=\mathrm{w}(a a *) \forall a \in M^{+}$.
vi. weight, if $\mathrm{w}(\lambda a+\mathrm{b})=\lambda \mathrm{w}(a)+\mathrm{w}(\mathrm{b}), \forall \lambda \geq 0, a, \mathrm{~b} \in M^{+}$

Consider the set $M^{+} \mathrm{w}=\left\{\mathrm{x} \in M^{+} \mid \mathrm{w}(\mathrm{x})<\infty\right\}$, We say that a linear functional $\omega$ is semi-finite if $M^{+} \mathrm{w}$ is weakly dense in $M^{+}$. In addition, a linear functional $\omega$ on $M$ is called a normal state (on $M$ ), if it is positive, normal and state.
Definition 2.5 A von Neumann algebra $M$ is said to be:
i. $\sigma$-finite, if $M$ has a faithful, normal and state.
ii. semi-finite, if $M$ has a faithful, normal and semi-finite trace.
iii. finite, if $M$ has a faithful, normal and tracial state.

Definition 2.6 Let $M$ be a von Neumann algebra on a Hilbert space H. A vector $\Omega \in H$ is cyclic for $M$ if the set $\{a \Omega$ : $a \in \mathrm{M}\}$ is dense in H and $\Omega \in \mathrm{H}$ is separating for $M$ if for all $a \in M, a \Omega=0$ for all $\Omega \in \mathrm{H}$ implies $a=0$.
Definition 2.7 Let $M$ be a von Neumann algebra and $\pi$ be a map from $M$ to $B(H)$, then $(\pi, H)$ is called $a^{*}$ representation of M if:
i. $\pi(\lambda a+\mu \mathrm{b})=\lambda \pi(a)+\mu \pi(\mathrm{b}), \forall a, \mathrm{~b} \in \mathrm{M}, \lambda, \mu \in \mathrm{C}$
ii. $\pi(a \mathrm{~b})=\pi(a) \pi(\mathrm{b}), \forall a, \mathrm{~b} \in \mathrm{M}$
iii. $\pi(a *)=\pi(a) *, \forall a \in \mathrm{M}$

For any positive linear functional $w$ on M , we get a *-representation ( $\pi_{w}, \mathrm{H}_{w}$ ) of M and this representation admits a cyclic vector $\Omega_{w}$ that is $\pi_{w}(M) \Omega_{w}=H_{w}$ such that $\omega(a)=<\pi_{w}(a) \Omega_{w}, \Omega_{w}>\forall \mathrm{a} \in \mathrm{M}$. This is called the GNS construction.
Definition 2.8 Let N be a von Neumann sub-algebra of M . P is called a projection of norm one from M onto N , if P is linear, $\mathrm{PM}=\mathrm{N}, \mathrm{Pb}=\mathrm{b}, \forall \mathrm{b} \in \mathrm{N}$, and $\|\mathrm{P} a\| \leq\|a\|, \forall a \in \mathrm{M}$.
That is, by a projection of norm one we mean a projection mapping from a Banach space onto its subspace whose norm is one.
Definition 2.9 Let N be a von Neumann sub-algebra of M . A conditional expectation mapping E from M to N is positive contraction $E: M \rightarrow N$ such that $E(b)=b$ and such that $E(b x)=b E(x)$ and $E(x b)=E(x) b \forall x \in M, b \in N(E$ is N -linear).
Therefore, a conditional expectation is a self-adjoint idempotent map from M to M (a projection onto N ) of norm one.
The conditional expectation does not always exists, [15] presents a condition for the existence of a conditional expectations as follows
Theorem 2.10 (Takesaki (1972), Theorem 1) Let $M$ be a von Neumann algebra and $\omega$ is faithful, semi-finite, normal weight on $\mathrm{M}+$. Let N be a von Neumann sub-algebra of M on which $\omega$ is semifinite. Then the following two statements are equivalent:
i. N is invariant under the modular automorphism group ot associated with $\omega$;
ii. There exists a $\sigma$-weakly continuous faithful projection E of norm one from M onto N such that
$\mathrm{w}(\mathrm{x})=\mathrm{w} \circ \mathrm{E}(\mathrm{x}) \quad \forall \mathrm{x} \in \mathrm{M}$
The projection E of norm one of M onto N is called the conditional expectations of M onto N with respect to $\omega$.
Definition 2.11 For each non-negative $t$, let $\left\{{\bar{M}{ }_{t} \Omega^{\|} \cdot \|}^{\prime}=H_{t}\right\}$ be the family of Hilbert subspaces of $\overline{M \Omega}{ }^{\|} \cdot \|=H$ such that
i. if $\mathrm{t}, \mathrm{s} \in \overline{\mathbb{R}}^{+}$with $\mathrm{s} \leq \mathrm{t}$ then $H_{s} \subseteq H_{t}$
ii. $\quad\left(\mathrm{U}_{t \geq 0} H_{t}\right)^{I I}=H$
iii. iii. $\cap_{\mathrm{t}>\mathrm{s}} H_{t}=H_{s}$

From the definition above, the family $\left\{H_{t}\right\}_{\mathrm{t} \in \overline{\mathbb{R}}^{+}}$is called a filtered Hilbert space.

## 3. Main Result

In this section, we present an analysis of a representation mapping and thereby introduce the representation mapping to stopping times and time projections.
Let H be a separable Hilbert space and let $\mathrm{B}(\mathrm{H})$ be the space of bounded linear operators on H , and let $M \subseteq \mathrm{~B}(\mathrm{H})$ a von Neumann algebra with a faithful normal state $\omega$ and with cyclic and separating vector $\Omega$ in $H$ such that $\omega(x)=<$ $\mathrm{x} \Omega, \Omega>, \forall \mathrm{x} \in M$. For each non-negative t , let $\left\{M_{t}: \mathrm{t} \in \overline{\mathbb{R}}^{+}\right\}$be the family of von Neumann sub-algebra of $M$ such that i. if $\mathrm{t}, \mathrm{s} \in \overline{R^{+}}$with $\mathrm{s} \leq \mathrm{t}$ then $M_{s} \subseteq M_{t}$
ii. the von Neumann algebra $M$ is generated by $\mathrm{U}_{\mathrm{t} \geq 0} M_{t}$ that is ${\overline{\mathrm{U}_{\mathrm{t} \geq 0} M_{t}}{ }^{\|} \cdot \|}^{\|}=M$
iii. $\cap_{\mathrm{t}>\mathrm{s}} M_{t}=M_{t}$

Finally, suppose there exists the family of faithful normal conditional expectations $\left\{E_{t}: \mathrm{t} \in \overline{\mathbb{R}}^{+}\right\}$from $M$ onto $M_{t}$ such that
iv. $\omega \circ E_{t}=\omega \quad \forall \mathrm{t} \in \overline{\mathbb{R}}^{+}$
v. $E_{t}(a x \mathrm{~b})=a E_{t}(x) \mathrm{b} \quad \forall a, \mathrm{~b} \in M_{t}, x \in M$
vi. $E_{t}(\mathrm{I})=\mathrm{I}$

Now we can define an inner product on $M$ by
$<a, \mathrm{~b}\rangle=\omega\left(\mathrm{b}^{*} a\right) \quad \forall a, \mathrm{~b} \in M \quad$ with $\quad \sqrt{\langle x, x\rangle}=\|x\|_{2}, x \in M$
$(M,<\ldots,>)$ is a pre-Hilbert space and we denotes its closure with respect to $\|.\|_{2}$ by $L^{2}(M)=\overline{M \Omega}\left\|^{\|} \cdot\right\|_{2}=H$. In a similar way, we can construct $L^{2}\left(M_{t}\right)$ and so $L^{2}\left(M_{t}\right) \subseteq L^{2}(M)$.
The map $\pi: \mathrm{M} \rightarrow \mathrm{B}\left(L^{2}(M)\right)$ defined by $\pi(a) \cdot \mathrm{b}=a$ b for $a \in \mathrm{Mb} \in L^{2}(M)$ and
$\pi(a) \mathrm{b}=\lim _{n \rightarrow \infty} a b_{n} \in L^{2}(M)$, for $b_{n} \rightarrow b \in L^{2}(M)$ is a well defined homomorphism since
$\pi(a+b) \cdot \mathrm{c}=(a+b) \mathrm{c}$
$=a \mathrm{c}+a \mathrm{~b}$
$=\pi(a) . \mathrm{c}+\pi(\mathrm{b}) . \mathrm{c}$
$\Rightarrow \pi(a+b)=\pi(a)+\pi(b)$
and
$\pi(a b) . \mathrm{c}=(a b) . \mathrm{c}$
$=a(\mathrm{bc})$
$=\pi(a)(\mathrm{bc})$
$=\pi(a) \pi(b) . \mathrm{c}$
$\Rightarrow \pi(a \mathrm{~b})=\pi(a) \pi(\mathrm{b})$
Furthermore, $\pi$ is normal positive map, suppose $a_{i} \rightarrow a$, then by definition of $\pi$, we have
$\pi\left(a_{i}\right) \cdot \mathrm{b}=a_{i} \mathrm{~b} \rightarrow a \mathrm{~b}=\pi(a) \mathrm{b}$
and so (1) imply that we have $\pi(a)=\pi\left(\sup _{i} a_{i}\right)=\sup _{i}\left(\pi\left(a_{i}\right)\right)$
making $\pi$ normal. Finally $\pi$ is injective since $\pi(a)=0 \Rightarrow \pi(a) . \mathrm{I}=0 \Rightarrow a=0$
From the above properties, we also observe that $\pi(M)$ is a von Neumann algebra using the fact that the unit ball of $\pi(M)$ is ultra-weakly compact. So $\pi(M)$ becomes an isometric copy of $M$. Furthermore, I is a cyclic and separating vector for $\pi(M)$ since $\{\pi(a) . \mathrm{I}: a \in M\}=M$ is dense in $L^{2}(M)$, and $\pi(a) \mathrm{I}=0 \Rightarrow a=0 \Rightarrow \pi(a)=0$
Remark 3.1 Let $\left\{E_{t}, \mathrm{t} \in \overline{\mathbb{R}}^{+}\right\}$be a family conditional expectation from $M$ onto $M_{t}$. Then a map $P_{t}$ defined on $L^{2}(M)$ by $P_{t}(a \Omega)=E_{t}(a) \Omega$, For each $\mathrm{t} \in \overline{\mathbb{R}}^{+}$is a projection from $L^{2}(M)$ onto $L^{2}\left(M_{t}\right)=\bar{M}_{t} \Omega\|\cdot\|$ and $\forall a \in M$ and $P_{t}$ lies in the commutant of $\pi(M)$.
To see this, we need to show that $P_{t}^{2}=P_{t}$ and $P_{t}^{*}=P_{t}$.
Now
Transactions of the Nigerian Association of Mathematical Physics Volume 14, (January -March., 2021), 27 - 32

$$
\begin{aligned}
& P_{t}^{2}(a \Omega)=P_{t}\left(P_{t}(a \Omega)\right) \\
& =P_{t}\left(E_{t}(a) \Omega\right)
\end{aligned}
$$

Since $E_{t}(a) \Omega=\mathrm{a} a \Omega \in L^{2}\left(M_{t}\right)=\bar{M}_{t} \Omega{ }^{\|} \cdot \|$. We have
$P_{t}\left(E_{t}(a) \Omega\right)=P_{t}(a \Omega) \Rightarrow P_{t}^{2}(a \Omega)=P_{t}(a \Omega)$
and so $P_{t}$ is an idempotent.
Also for $\mathrm{a}, \mathrm{b} \in \mathrm{M}$ we have
$\left\langle P_{t}(\mathrm{a} \Omega), \mathrm{b} \Omega\right\rangle=\left\langle P_{t}(\mathrm{a} \Omega), P_{t}(\mathrm{~b} \Omega)+\left(1-P_{t}\right)(\mathrm{b} \Omega)\right\rangle$
$=\left\langle P_{t}(\mathrm{a} \Omega), P_{t}(\mathrm{~b} \Omega)\right\rangle+\left\langle P_{t}(\mathrm{a} \Omega),\left(1-P_{t}\right)(\mathrm{b} \Omega)\right\rangle$
Since $P_{t}(\mathrm{a} \Omega) \in L^{2}\left(M_{t}\right)$ then $\left(1-P_{t}\right)(\mathrm{b} \Omega) \in L^{2}\left(M_{t}\right)^{\perp} \Rightarrow\left\langle P_{t}(\mathrm{a} \Omega),\left(1-P_{t}\right)(\mathrm{b} \Omega)\right\rangle=0$ and so we have $\left\langle P_{t}(\mathrm{a} \Omega), \mathrm{b} \Omega\right\rangle=$ $\left\langle P_{t}(\mathrm{a} \Omega), P_{t}(\mathrm{~b} \Omega)\right\rangle$
again
$\left\langle\mathrm{a} \Omega, P_{t}(\mathrm{~b} \Omega)\right\rangle=\left\langle P_{t}(\mathrm{a} \Omega)+\left(1-P_{t}\right)(\mathrm{a} \Omega), P_{t}(\mathrm{~b} \Omega)\right\rangle$
$=\left\langle P_{t}(\mathrm{a} \Omega), P_{t}(\mathrm{~b} \Omega)\right\rangle+\left\langle\left(1-P_{t}\right)(\mathrm{a} \Omega), P_{t}(\mathrm{~b} \Omega)\right\rangle$
also $\left\langle\left(1-P_{t}\right)(\mathrm{a} \Omega), P_{t}(\mathrm{~b} \Omega)\right\rangle=0$
$\left\langle\mathrm{a} \Omega, P_{t}(\mathrm{~b} \Omega)\right\rangle=\left\langle P_{t}(\mathrm{a} \Omega), P_{t}(\mathrm{~b} \Omega)\right\rangle$
and so from 2 and 3 we have that $\quad\left\langle P_{t}(\mathrm{a} \Omega), \mathrm{b} \Omega\right\rangle=\left\langle\mathrm{a} \Omega, P_{t}(\mathrm{~b} \Omega)\right\rangle$
and since $\quad\left\langle P_{t}(\mathrm{a} \Omega), \mathrm{b} \Omega\right\rangle=\left\langle\mathrm{a} \Omega, P_{t}^{*}(\mathrm{~b} \Omega)\right\rangle$
$\Rightarrow P_{t}^{*}=P_{t}$ and so $P_{t}$ is self-adjoint and hence, $P_{t}$ an orthogonal projection onto L2(Mt).
Now we show that $P_{t}$ lies in the commutant of $\pi(\mathrm{M})$. To see this, we have
$P_{t}(\mathrm{xy} \Omega)=\mathrm{Et}(\mathrm{xy}) \Omega, \quad \forall \mathrm{x} \in \pi(\mathrm{M}), \mathrm{y} \in \pi(\mathrm{M})$
$=\operatorname{Et}(\mathrm{x}) \mathrm{y} \Omega$
$=\mathrm{yEt}(\mathrm{x}) \Omega$
$=\mathrm{y} P_{t}(\mathrm{x} \Omega)$
Since $M \Omega$ is dense in $H$, then the result follows.
Here, we use the representation mapping to define stopping times, time projections and analyse some of their properties.
Definition 3.2 A stopping time, $\tau$, adapted to the filtration of von Neumann algebras $\left(\pi\left(M_{t}\right)\right)_{\mathrm{t} \in \overline{\mathbb{R}}^{+}}$is an increasing family $\left\{\pi\left(q_{t}\right)\right\}_{\mathrm{t} \in \overline{\mathbb{R}}^{+}}$of projections in M such that:
i. $\quad \tau(\mathrm{t})=\pi\left(q_{t}\right) \in \pi\left(M_{t}\right)^{\text {proj }}$
ii. $\quad \tau(0)=\pi\left(q_{0}\right)=0$
iii. $\tau(\infty)=\pi\left(q_{\infty}\right)=$ I

Definition 3.3 Let $\tau=\pi\left(q_{t}\right)_{\mathrm{t} \in \overline{\mathbb{R}}^{+}}$and $\sigma=\pi\left(r_{t}\right)_{\mathrm{t} \in \overline{\mathbb{R}}^{+}}$be stopping times. We can define an order $\tau \leq \sigma \Leftrightarrow \pi\left(r_{t}\right) \leq \pi\left(q_{t}\right)$. We define $\tau \wedge \sigma=\pi\left(q_{t}\right) \vee \pi\left(r_{t}\right)$ and $\tau \vee \sigma=\pi\left(q_{t}\right) \wedge \pi\left(r_{t}\right)$.
Let $\Theta$ denote the set of all finite partitions of $[0, \infty]$. Then for $\theta \in \Theta$ say $\theta=\left\{t_{0}, \ldots, t_{n}\right\}$, we define an operator $\mathrm{P}_{\tau(\theta)}$ on H as
$\mathrm{P}_{\tau(\theta)}=\sum_{i=1}^{n} \pi\left(q_{t_{i}}-q_{t_{i-1}}\right) P_{t_{i}}=\sum_{i=1}^{n} \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}}$
Theorem 3.4 Let $\tau(\mathrm{t})=\pi\left(q_{t}\right)$ be a stopping time. Then
(i) $P_{\tau(\theta)}$ is an orthogonal projection
(ii) if $\theta_{1}, \theta_{2} \in \Theta$ with $\theta_{2} \supseteq \theta_{1}$ then $\mathrm{P}_{\tau\left(\theta_{2}\right)} \leq \mathrm{P}_{\tau\left(\theta_{1}\right)}$
(iii) if $\sigma=\pi\left(r_{t}\right)$ is another stopping time with $\tau \leq \sigma$ then $\mathrm{P}_{\tau(\theta)} \leq \mathrm{P}_{\sigma(\theta)}$

## Proof.

(i) Let $\tau=\pi\left(q_{t}\right), \xi \in \mathrm{H}$ and $\theta=\left\{t_{0}, t_{1}, \ldots, t_{n}\right\} \in \Theta$ then

$$
\begin{aligned}
\mathrm{P}_{\tau(\theta)} \circ \mathrm{P}_{\tau(\theta)}(\xi)= & \sum_{j=1}^{n} \Delta \pi\left(q_{t_{j}}\right) P_{t_{j}}\left(\sum_{i=1}^{n} \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}}\right)(\xi) \\
& =\sum_{j=1}^{n} \sum_{i=1}^{n} \Delta \pi\left(q_{t_{j}}\right) P_{t_{j}} \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}}(\xi) \\
& =\sum_{j-1}^{n} \sum_{i=1}^{n} P_{j} \Delta \pi\left(q_{t_{j}}\right) \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}} \xi \\
& =\sum_{i=1}^{n} P_{t_{i}} \Delta \pi\left(q_{t_{i}}\right) \xi \\
& =\mathrm{P}_{\tau(\theta)}(\xi)
\end{aligned}
$$

Since $\Delta \pi\left(q_{t_{j}}\right) \Delta \pi\left(q_{t_{i}}\right)=0$ for $\mathrm{i} \neq \mathrm{j}$, then we have
$P_{\tau(\theta)} \circ P_{\tau(\theta)}=P_{\tau(\theta)}$ that is $P_{\tau(\theta)}^{2}=P_{\tau(\theta)}$. Thus $\mathrm{P}_{\tau(\theta)}$ is an idempotent.
Also for $\xi, \eta \in \mathrm{H}$, we have
$<\mathrm{P}_{\tau(\theta)} \eta, \xi>=<\sum_{i=1}^{n} \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}} \eta, \xi>$
Transactions of the Nigerian Association of Mathematical Physics Volume 14, (January -March., 2021), 27 -32

```
\(=\sum_{i=1}^{n}\left\langle\eta, P_{t_{i}} \Delta \pi\left(q_{t_{i}}\right) \xi>\right.\)
    \(=\sum_{i=1}^{n}\left\langle\eta, \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}}\right\}>\)
    \(=\left\langle\eta, \sum_{i=1}^{n} P_{t_{i}} \Delta \pi\left(q_{t_{i}}\right) \xi\right\rangle\)
        \(=\left\langle\eta, \mathrm{P}_{\tau(\theta)} \xi\right\rangle\)
that is \(\left\langle\mathrm{P}_{\tau(\theta)} \eta, \xi\right\rangle=\left\langle\eta, \mathrm{P}_{\tau(\theta)} \xi\right\rangle\)
but
\(\left\langle\mathrm{P}_{\tau(\theta)} \eta, \xi\right\rangle=<\eta, P_{\tau(\theta)}^{*} \xi>\)
```

From (5) and (6) we see that $\quad P_{\tau(\theta)}^{*}=P_{\tau(\theta)}$. Hence, $\mathrm{P}_{\tau(\theta)}$ is a self-adjoint establishing (i).
(ii) Suppose $\theta_{2}=\theta_{1} \cup\{\mathrm{~s}\}$ where $\theta_{1}=\left\{t_{0}<\ldots t_{n}\right\}$ with $t_{i}<t_{i+1}$ and $\mathrm{s} \in\left\{t_{r}, t_{r+1}\right\}, \mathrm{r}+1<\mathrm{n}$. Then for $\xi \in \mathrm{H}$,
$\mathrm{P}_{\tau\left(\theta_{1}\right)} \circ \mathrm{P}_{\tau\left(\theta_{2}\right)}(\xi)=\sum_{j=1}^{n} \Delta \pi\left(q_{t_{j}}\right) P_{t_{j}}\left(\sum_{i=1}^{r} \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}}(\xi)\right)$

$$
\begin{aligned}
& +\sum_{j=1}^{n} \Delta \pi\left(q_{t_{j}}\right) P_{t_{j}} \pi\left(q_{t_{s}}-q_{t_{r}}\right) P_{t_{s}}(\xi) \\
& +\sum_{j=1}^{n} \Delta \pi\left(q_{t_{j}}\right) P_{t_{j}} \pi\left(q_{t_{r+1}}-q_{t_{s}}\right)_{t_{r_{1}}}(\xi) \\
& +\sum_{j=1}^{n} \Delta \pi\left(q_{t_{j}}\right) P_{t_{j}}\left(\sum_{j=1}^{n} \Delta \pi\left(q_{t_{j}}\right) P_{t_{j}}(\xi)\right)
\end{aligned}
$$

Using the fact that $P_{t}$ lies in the commutant of $\pi(\mathrm{M})$ and the orthogonality of $\Delta \pi\left(q_{t_{j}}\right)$ and $\Delta \pi\left(q_{t_{i}}\right)$ and for $\theta_{1} \subseteq \theta_{2}$ we have

$$
\begin{aligned}
& \mathrm{P}_{\tau\left(\theta_{1}\right)} \circ \mathrm{P}_{\tau\left(\theta_{2}\right)}(\xi)=\sum_{j=1}^{n} \Delta \pi\left(q_{t_{j}}\right) P_{t_{j}}(\xi)+\pi\left(q_{t_{s}}-q_{t_{r}}\right) P_{t_{s}}(\xi) \\
& +\pi\left(q_{t_{r+1}}-q_{t_{s}}\right) P_{t_{r+1}}(\xi)+\sum_{j=1}^{n} \Delta \pi\left(q_{t_{j}}\right) P_{t_{j}}(\xi) \\
& \quad=\mathrm{P}_{\tau\left(\theta_{2}\right)}(\xi) \Rightarrow \mathrm{P}_{\tau\left(\theta_{1}\right)}{ }^{\circ} \mathrm{P}_{\tau\left(\theta_{2}\right)}=\mathrm{P}_{\tau\left(\theta_{2}\right)}
\end{aligned}
$$

and so $\mathrm{P}_{\tau\left(\theta_{2}\right)} \leq \mathrm{P}_{\tau\left(\theta_{1}\right)}$
$\Rightarrow\left(\mathrm{P}_{\tau(\theta)}\right) \theta \in \Theta$ is a decreasing net of orthogonal projections and so, the infimum exists and let $P_{\tau}=\inf _{\theta \in \Theta} \mathrm{P}_{\tau(\theta)}$.
Definition 3.5 For a stopping time $\tau=\left(\pi\left(q_{t}\right)\right)_{\mathrm{t} \in \overline{\mathbb{R}}^{+}}$we can define the time projection at $\tau, P_{\tau}$, as
$P_{\tau}=\inf _{\theta \in \Theta} \sum_{i=1}^{n} \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}}(\xi)=\inf _{\theta \in \Theta} \mathrm{P}_{\tau}(\theta)$
(iii) Given $\sigma \geq \tau$, let $\sigma=\pi\left(r_{t}\right)$. So that $\pi\left(r_{t}\right) \leq \pi\left(q_{t}\right)$ for each $\mathrm{t} \in \overline{\mathbb{R}}^{+}$. Let $\theta \in \Theta$ be as in (ii) above say, then
$\sum_{i=1}^{n} \Delta \pi\left(q_{t_{i}}\right)=\sum_{i=1}^{n} \pi\left(q_{t_{i}}-q_{t_{i-1}}\right)$
$=\pi\left(q_{t_{1}}\right)-\pi\left(q_{t_{0}}\right)+\pi\left(q_{t_{2}}\right)-\pi\left(q_{t_{1}}\right)+\pi\left(q_{t_{3}}\right)-\pi\left(q_{t_{2}}\right)+\pi\left(q_{t_{4}}\right)-\pi\left(q_{t_{3}}\right)$
$+\ldots+\pi\left(q_{t_{n-3}}-\pi\left(q_{t_{n-2}}\right)+\pi\left(q_{t_{n-1}}\right)-\pi\left(q_{t_{n-2}}\right)+\pi\left(q_{t_{n}}\right)-\pi\left(q_{t_{n-1}}\right)\right.$
$=\pi\left(q_{t_{n}}\right)-\pi\left(q_{t_{0}}\right)$
$=\mathrm{I}-0 \quad$ where $\pi\left(q_{t_{0}}\right)=0$ and $\pi\left(q_{t_{n}}\right)=\mathrm{I}$
$=\mathrm{I}$
and so we have
$\mathrm{I}=\sum_{i=1}^{n} \Delta \pi\left(q_{t_{i}}\right)=\sum_{i=1}^{n} \Delta \pi\left(r_{t_{i}}\right)$
Now $\quad \mathrm{P}_{\mathrm{\tau}(\theta)}{ }^{\circ} \mathrm{P}_{\sigma(\theta)}=\sum_{i=1}^{n} \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}}\left(\sum_{j=1}^{n} \Delta \pi\left(r_{t_{j}}\right) P_{t_{j}}\right)$
But $\quad \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}} \sum_{j=1}^{n} \Delta \pi\left(r_{t_{j}}\right) P_{t_{j}}=\sum_{j=1}^{n} \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}} \Delta \pi\left(r_{t_{j}}\right)$
from the fact that $P_{t}$ lies in the commutant of $\pi(\mathrm{M})$ and observing that $\Delta \pi\left(r_{t_{j}}\right) \leq \Delta \pi\left(q_{t_{i}}\right)$ for $\mathrm{j} \leq \mathrm{i}-1$, we see that

$$
\begin{aligned}
\mathrm{P}_{\tau(\theta)} \circ \mathrm{P}_{\sigma(\theta)} & =\sum_{i=1}^{n} \sum_{j=1}^{n} \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}} \Delta \pi\left(r_{t_{j}}\right) P_{t_{j}} \\
& =\sum_{i=1}^{n}\left(\sum_{j=1}^{n} \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}} \Delta \pi\left(r_{t_{j}}\right)+\Delta \pi\left(q_{t_{i}}\right) P_{t_{i}}\left(I-\sum_{k=1}^{n} \Delta \pi\left(r_{t_{k}}\right)\right)\right. \\
& =\sum_{i=1}^{n} \Delta \pi\left(q_{t_{i}}\right) P_{t_{i}}
\end{aligned}
$$

$$
=P_{\tau(\theta)}
$$

Hence $\mathrm{P}_{\tau(\theta)} \leq \mathrm{P}_{\sigma(\theta)}$ establishing (iii)
Theorem 3.6 Let $\tau=\pi\left(q_{t}\right)$ and $\sigma=\pi\left(r_{t}\right)$ be stopping times, and let $\theta \in \Theta$. Then
$P_{(\sigma \vee \tau)(\theta)}=P_{\sigma(\theta)} \vee P_{\tau(\theta)}$ and $P_{(\sigma \wedge \tau)(\theta)}=P_{\sigma(\theta)} \wedge P_{\tau(\theta)}$
Proof. Suppose that $\theta=\left\{t_{0}, t_{1}, \ldots, t_{n}\right\} \in \Theta$, then for any $\xi \in \mathrm{H}$, we have
$P^{\perp}{ }_{\sigma(\theta)} \xi=\sum_{i=1}^{n} \pi\left(r_{t_{i}}\right) \Delta P_{t_{i}} \xi$
$=\sum_{i=1}^{n} \pi\left(r_{t_{i}}\right)\left(P_{t_{i}}-P_{t_{i-1}}\right) \xi$
and hence

$$
\begin{aligned}
& P^{\perp}{ }_{\tau(\theta)} \circ P^{\perp}{ }_{\sigma(\theta)} \xi=\sum_{j=1}^{n} \pi\left(q_{t_{j}}\right) \Delta P_{t_{j}}\left(\sum_{i=1}^{n} \pi\left(r_{t_{i}}\right) \Delta P_{t_{i}} \xi\right) \\
& \quad=\sum_{j=1}^{n} \sum_{i=1}^{n} \pi\left(q_{t_{j}}\right) \Delta P_{t_{j}} \pi\left(r_{t_{i}}\right) \Delta P_{t_{i}} \xi
\end{aligned}
$$

Transactions of the Nigerian Association of Mathematical Physics Volume 14, (January-March., 2021), 27-32

$$
=\sum_{j=1}^{n} \sum_{i=1}^{n} \pi\left(q_{t_{j}}\right) \Delta E_{t_{j}}\left(\pi\left(r_{t_{i}}\right)\right) \Delta P_{t_{j}} \Delta P_{t_{i}} \xi
$$

Where $\Delta E_{t_{j}}=E_{t_{j}}-E_{t_{j-1}}$ and the conditional expectation is $E_{t}=\sum_{j=1}^{n} \pi\left(r_{t_{j}}\right) \pi\left(q_{t_{j}}\right) \Delta P_{t_{j}} \xi$
since $\Delta P_{t_{i}} \Delta P_{t_{j}}=0$ for $\mathrm{i} \neq \mathrm{j}$ It follows that
$\left(P^{\perp}{ }_{\tau(\theta)}{ }^{\circ} P^{\perp}{ }_{\sigma(\theta)}\right)^{k} \xi=\sum_{j=1}^{n}\left(\pi\left(r_{t_{j}}\right) \pi\left(q_{t_{j}}\right)\right)^{k} \Delta P_{t_{j}} \xi$
for any $k=1,2, \ldots$
Letting $\mathrm{k} \rightarrow \infty$, we obtain
$P^{\perp}{ }_{\tau(\theta)} \wedge P^{\perp}{ }_{\sigma(\theta)} \xi=\sum_{j=1}^{n}\left(\pi\left(r_{t_{j}}\right) \wedge \pi\left(q_{t_{j}}\right)\right) \Delta P_{t_{j}} \xi$
$=\mathrm{P}_{(\tau \vee \sigma)(\theta)} \xi$
Taking the orthogonal complements, we see that
$P_{\tau(\theta)} \vee P_{\sigma(\theta)}=P_{(\tau \vee \sigma)(\theta)}$.
For the infimum, we begin with

$$
P_{\sigma(\theta)} \xi=P_{0} \xi+\sum_{i=1}^{n} \pi\left(r_{t_{i}}^{\perp}\right) \Delta P_{t_{i}} \xi
$$

As above we see that
$\left(\mathrm{P}_{\tau(\theta)}{ }^{\circ} \mathrm{P}_{\sigma(\theta)}\right)^{k} \xi=\sum_{i=1}^{n}\left(\pi\left(q_{t_{i}}{ }^{\perp}\right) \pi\left(r_{t_{i}}{ }^{\perp}\right)\right)^{k} \Delta P_{t_{i}} \xi$
Letting $\mathrm{k} \rightarrow \infty$, we get
$\mathrm{P}_{\tau(\theta)} \wedge \mathrm{P}_{\sigma(\theta)}=\mathrm{P}_{(\tau \wedge \sigma)(\theta)}$
Theorem 3.7 (optional stopping) For stopping times $\tau$, $\sigma$ with $\tau \leq \sigma$, we have $\mathrm{P}_{\tau} \leq \mathrm{P}_{\sigma}$.
Proof.
From theorem 3.4 (iii) $\mathrm{P}_{\tau(\theta)} \leq \mathrm{P}_{\sigma(\theta)} \forall \theta$. The result now follows by taking the limit as $\theta$ refines.
Corollary 3.8 For any stopping times $\tau, \sigma$ we have $\mathrm{P}_{\tau} \wedge \mathrm{P}_{\sigma}=\mathrm{P}_{(\tau \wedge \sigma)}$.
Proof. we have $\tau \wedge \sigma \leq \tau$ and so $\mathrm{P}_{(\tau \wedge \sigma)} \leq \mathrm{P}_{\tau}$ (by optional stopping theorem).
Similarly, $\mathrm{P}_{(\tau \wedge \sigma)} \leq \mathrm{P}_{\sigma}$. Hence $\mathrm{P}_{(\tau \wedge \sigma)} \leq \mathrm{P}_{\tau} \wedge \mathrm{P}_{\sigma}$. On the other hand, for any $\theta \in \Theta$,
$\mathrm{P}_{\tau(\theta)} \wedge \mathrm{P}_{\sigma(\theta)}=\mathrm{P}_{(\tau \wedge \sigma)(\theta)} \quad$ (By theorem 3.5)
Hence
$P_{\tau} \wedge P_{\sigma} \leq P_{\tau(\theta)} \wedge P_{\sigma(\theta)}=P_{(\tau \wedge \sigma)(\theta)} \quad \forall \theta \in \Theta$
giving
$\mathrm{P}_{\tau} \wedge \mathrm{P}_{\sigma} \leq \mathrm{P}_{(\tau \wedge \sigma)}$

## Conclusion

In conclusion, we present the theory of non-commutative stopping time and time projection on a filtered Hilbert space where we define our representation mapping on the filtered Hilbert space using the general definition of filtration and thereby introduce the representation mapping on stopping times and time projection. We also prove the optional stopping theorem.

## Acknowledgement

I sincerely appreciate my supervisor Professor A. A. Tijjani for his quality insight to this research work.
