## A Three Step Explicit Method for Direct Solution of Third Order Differential Equations

Familua A.B.<br>Department of Mathematical Sciences, Federal University of Technology, Akure.

#### Abstract

This study produces a three step discrete Linear Multistep Method for Direct solution of third order initial value problems of ordinary differential equations of the form $y^{\prime \prime \prime}=$ $f\left(x, y, y^{\prime}, y^{\prime \prime}\right)$. Taylor series expansion technique was adopted in the development of the method. The differential system from the basis polynomial function to the problem is expanded by Taylor series expansion approach. The method is consistent and zero-stable. This is tested on a number of problems to show the accuracy and efficiency. A predictor of $y_{n+k}$ where $K>3$ in the main method is also proposed.

Keywords: Linear multistep method, basis function, Taylor series expansion, Predictor, discrete method, Zero stable.

### 1.0 Introduction:

The solution of third order differential equation of initial value problem

$$
\begin{equation*}
y^{\prime \prime \prime}=f\left(x, y, y^{\prime}, y^{\prime \prime}\right) \tag{1}
\end{equation*}
$$

is considered in this paper. Literature has revealed or showed that the commonest method for solving a $3^{\text {rd }}$ order ordinary differential equation is by reduction of the problem into a system of first order ordinary differential equation of the form

$$
\begin{equation*}
\mathrm{y}^{\prime}=\mathrm{f}(\mathrm{x}, \mathrm{y}), \mathrm{y}\left(\mathrm{x}_{0}\right)=\mathrm{y}_{0} \tag{2}
\end{equation*}
$$

There are several numerical methods that can cater for the problem in equation (2). They are $[1,3,4,5,6]$ proposed a continuous method for (1). The results obtained showed an order 5 scheme for $\mathrm{k}=3$. The conventional method which involves the reduction of (1) into a system of first order ordinary differential equation suffers some major setbacks. The setbacks include computational burden and cost implication.
Furthermore, a more serious drawback to such technique arises when the given system of equations to be solved cannot be solved explicitly for the derivatives of the highest order. [2]. The method then becomes inefficient and uneconomical for a general purpose application.
In this paper a three step explicit Linear multistep method of the form

$$
\begin{equation*}
y_{n+k} \sum_{i=0}^{k-1} \alpha_{j} y_{n+j} \quad h^{3} \sum_{i=0}^{k-1} \beta_{j} y^{m}{ }_{n+j} \quad k \geq 3 \tag{3}
\end{equation*}
$$

is to be developed for direct solution of third order initial value problems of ordinary differential equations of the form

$$
\begin{equation*}
y^{\prime \prime \prime}=\mathrm{f}\left(\mathrm{x}, \mathrm{y} \cdot \mathrm{y}^{\prime}, \mathrm{y}^{\prime \prime}\right) ; \quad \mathrm{y}\left(\mathrm{x}_{0}\right)=\mathrm{y}_{0}, \mathrm{y}^{\prime}\left(\mathrm{x}_{0}\right)=\mathrm{y}^{\prime}(0), \mathrm{y}^{\prime \prime}\left(\mathrm{x}_{0}\right)=\mathrm{y}^{\prime \prime} \tag{4}
\end{equation*}
$$

## The Method

The method discussed in this paper is motivated by the Linear multistep method

$$
\begin{equation*}
\sum_{i=0}^{k-1} \alpha_{j} y_{n+j} h \sum_{i=0}^{k-1} \tag{5}
\end{equation*}
$$

Proposed by Adams (1883) for numerical solution of $\mathrm{I}^{\text {st }}$ order ordinary differential equation (2) In this paper, equation (5) is redefined for the $3^{\text {rd }}$ order ordinary differential equation $y^{\prime \prime \prime}=f\left(x, y \cdot y^{\prime}, y^{\prime \prime}\right)$ as

$$
\begin{equation*}
y_{n+k}=\sum_{i=0}^{k-1} \alpha_{j} y_{n+j}+h^{3} \sum_{i=0}^{k-1} \beta_{j} y^{m}{ }_{n+j} \tag{6}
\end{equation*}
$$

Corresponding authors: Familua A.B. : E-mail: -, Tel. +2348127380293

Where the parameters $\alpha_{j}$ and $\beta_{\mathrm{j}}$ are to be determined to ensure that the resultants methods are Consistent, Zero-stable and Convergent, where $\alpha_{k}=1$ and $\alpha_{0}$ and $\beta_{0}$ are not both zero. Assuming that a truncation error $T_{n+k}$ defined as

$$
\begin{equation*}
T_{n+k}=\sum_{i=0}^{k=1} \alpha_{j} y_{n+j}+h^{3} \sum_{i=0}^{k-1} \beta_{j} y^{m}{ }_{n+j} \tag{7}
\end{equation*}
$$

is made at each step of application of the method for solution of (1). Then the parameter $\alpha_{j}$ 's and $\beta_{j}{ }^{\prime} s, j=0(1) k$ can be determined as to ensure that $T_{n+k}$ is minimum. The procedures are as follows:-
Adopting Taylor series expansion of $\mathrm{y}_{\mathrm{n}+\mathrm{k},} \mathrm{y}_{\mathrm{n}+\mathrm{j}}$ and $\mathrm{y}_{\mathrm{n}+\mathrm{j}} \mathrm{j}=0(1) \mathrm{k}-1$ about point $\left(\mathrm{x}_{\mathrm{n}}, \mathrm{y}_{\mathrm{n}}\right)$ to have

$$
\begin{align*}
& y_{n+k}=y_{n}+(k h) y_{n}{ }^{1}+\frac{(k h)^{2} y_{n}{ }^{2}}{2!}+\frac{(k h) y_{n}{ }^{3}}{3!}+\frac{(k h)^{4} y_{n}{ }^{4}}{4!}+\cdots \frac{(k h)^{p} y_{n}{ }^{p}}{p!}+\frac{(k h)^{p+1} y_{n}{ }^{2}}{(p+1)!}+\frac{(k h)^{p+1} y_{n}{ }^{2}}{(p+2)!}+ \\
& 0\left(h^{p+3}\right)  \tag{8}\\
& y_{n+k}=y_{n}+(j h) y_{n}{ }^{1}+\frac{(j h)^{2} y_{n}{ }^{2}}{2!}+\frac{(j h)^{3} y_{n}{ }^{3}}{3!}+\frac{(j h)^{4} y_{n}{ }^{4}}{4!}+\cdots \frac{(j h)^{p} y_{n}{ }^{p}}{p!}+ \\
& \quad \frac{(j h)^{p+2} y_{n}{ }^{p+1}}{(p+1)!}+\frac{(j h)^{p+2} y_{n}{ }^{p+2}}{(p+2)!}+0\left(h^{p+3}\right)  \tag{9}\\
& \left.y^{m}\right) \\
& y_{n+j}=y_{n}{ }^{3}+(j h) y_{n}{ }^{4}+\frac{(j h)^{2} y_{n}(5)}{2!}+\frac{(j h)^{3} y_{n}(6)}{3!}+\ldots \frac{(j h) y_{y_{n} p}}{p!}+  \tag{10}\\
& \frac{(j h) y_{n}{ }^{p+1}}{(p+1)!}+\frac{(h h) y_{n}{ }^{p+2}}{(p+2)!}+0\left(h^{p+3)}\right.
\end{align*}
$$

When the above expansions; that is (equations 8,9 and 10), are inserted into the error equation
(7), and terms in equal powers of $h$ are combined, we get,
$T_{n+k}=$
$\left[1-\sum_{i=0}^{k-1} \alpha_{j}\right] y_{n}+\left[1-\sum_{i=0}^{k-1} j \alpha_{j}\right] h y^{1}{ }_{n}+\left[\frac{k^{2}}{2} \sum_{i=0}^{k-1} \alpha_{j}\right] h^{2} y^{2}+\left[\frac{k^{3}}{3!} \sum_{i=0}^{k-1} \frac{(j)^{3}}{3!} \alpha_{j} \sum_{i=0}^{k-1} \beta_{j}\right] h^{3} y^{3}+\left[\frac{k^{4}}{4!} \sum_{i=0}^{k-1} \frac{(j)^{4}}{4!} \alpha_{j} \sum_{i=0}^{k-1} \beta_{j}\right] h^{4} y^{4}+$ $\left[\frac{k^{p}}{p!}-\sum_{i=0}^{k-1} \frac{1()^{p}}{p!} \alpha_{j}-\sum_{i=0}^{k-1} \beta_{j}\right] h^{p} y^{p} 0\left(h^{p+3}\right)$

This can be compactly written as

$$
\begin{equation*}
\mathrm{T}_{\mathrm{n}+\mathrm{k}}=\mathrm{C}_{\mathrm{o}} \mathrm{y}_{\mathrm{n}}+\mathrm{C}_{1} \mathrm{hy}^{1} \mathrm{n}+\mathrm{C}_{2} \mathrm{~h}^{2} \mathrm{y}_{\mathrm{n}}{ }^{2}+\ldots \mathrm{C}_{\mathrm{p}} \mathrm{~h}^{\mathrm{p}}+\mathrm{C}_{\mathrm{p}+1} \mathrm{~h}^{\mathrm{p}+1}+\mathrm{C}_{\mathrm{p}+2} \mathrm{~h}^{\mathrm{p}+2}+\mathrm{O}\left(\mathrm{~h}^{\mathrm{p}+3}\right) \tag{12}
\end{equation*}
$$

Where

$$
\begin{align*}
& C_{0}=1-\sum_{i=0}^{K-1} \alpha_{j} y_{n} \\
& \quad C_{1}=K-\sum_{i=0}^{K-1} J \alpha_{j} h y_{n}^{\prime} \\
& C_{2}=\frac{k^{2}}{2!}-\sum_{i=0}^{k-1}(J)^{2} \alpha_{j} h^{2} y^{2}{ }_{n} \\
& C_{2}=\frac{k^{p}}{p!}-\sum_{i=0}^{k-1} \frac{()^{2} \alpha_{j}}{p!}-\sum_{i=0}^{k-1} \frac{j p-2 \alpha_{j}}{(p-2)!} \beta_{j} h^{2} y^{2}{ }_{n} \ldots O\left(h^{p+1}\right) \tag{13}
\end{align*}
$$

Solving equations 11,12 and 13 to obtain the parameters $\alpha{ }^{j}$ 's and $\beta \mathrm{j}$ 's by using guassian elimination method.
Setting $k=3$ in equation (6) we have a 3-step scheme of the form

$$
\begin{equation*}
y_{n+3}=\alpha_{0} y_{n}+\alpha_{1} y_{n+1}+\alpha_{2} y_{n+2}+h^{3}\left[\beta_{0} y_{n}^{\prime \prime \prime}+\beta_{1} y^{\prime \prime \prime}{ }_{n+1}+\beta_{2} y^{\prime \prime \prime}{ }_{n+2}\right] \tag{14}
\end{equation*}
$$

With local truncation error
$T_{n+3}=y_{n+3}(-\alpha 1-2 \alpha 2) h^{1}{ }_{n}+\left(9 / 2-\alpha_{1 / 2}-2 \alpha_{2}\right) h^{2} y^{2}{ }_{n}+\left(27 / 6-\alpha 1 / 6-8 \alpha 2 / 6-\beta_{0}-\beta_{1}-\beta_{2}\right) h^{3} y^{3}{ }_{n}+\left(81 / 24-\alpha 1 / 24-16 / 24 \alpha 2-\beta_{1}-2 \beta_{2}\right) h^{4} y^{4}{ }_{n}$ $+\left(243 / 120-\alpha 1 / 120-32 / 120 \alpha 2-\beta_{1 / 2}-2 \beta_{2}\right) h^{5} y^{5}{ }_{n}+\left(729 / 720-\alpha 1 / 720-64 / 120 \alpha 2-\beta_{1} 6-8 \beta_{2}\right) h^{6} y^{6}{ }_{n}+(2187 / 5040-\alpha 1 / 5040-128 \alpha 2 / 5040-$ $\left.\beta_{1 / 24-16 / 24} \beta_{2}\right) \mathrm{h}^{7} \mathrm{y}_{\mathrm{n}}^{7} \ldots \mathrm{O}(\mathrm{h})^{8}$
Solving this by Gaussian elimination technique on the system of liner equation; the values of $\alpha_{j} \mathrm{~s}$ and $\beta_{j} \mathrm{~s}$ are obtained as $\alpha_{0}=1$, $\alpha_{1}=-3, \alpha_{2}=3, \beta_{0}=0, \beta_{1}=1 / 2, \beta_{3}=0$
Substituting the values of these parameters into the expansion in (14) the general 3-step linear multistep method is obtained as
$\mathrm{y}_{\mathrm{n}+3}=3 \mathrm{y}_{\mathrm{n}+2}-3 \mathrm{y}_{\mathrm{n}+1}+\mathrm{y}_{\mathrm{n}}+\frac{h^{3}}{2} \quad\left[\mathrm{f}_{\mathrm{n}+2}+\mathrm{f}_{\mathrm{n}+1}\right]$
Order $\mathrm{P}=5$, and error constant $\mathrm{C}_{7}=1 / 240$ or 0.0041667 and interval of periodicity $\mathrm{x}(\theta)=(0, \infty)$

## Predictors for the methods:

To implement the scheme(method) (17) for the solution of third order initial value problem of type (4) there is need to develop the predictors for the evaluation of $y_{n+2}, y_{n+1}$ and its derivatives $y_{n+2}, y_{n+1}$ in order to evaluate $f_{n+j}=f\left(x_{n+j}, y_{n+j}, y_{n+j}\right) j=$ 1,2 . These predictors must have the same order of accuracy as the main method in order to avoid initial data error in the computation.

$$
\begin{equation*}
y_{n+1}=y_{n}+\frac{(h)^{2} y_{n}{ }^{2}}{2!}+\frac{(h)^{3} y_{n}{ }^{3}}{3!}+\frac{(2 h)^{4} y_{n}{ }^{4}}{4!}+\frac{(2 h)^{5} y_{n}{ }^{5}}{5!}+\ldots O(h)^{6} \tag{18}
\end{equation*}
$$

Journal of the Nigerian Association of Mathematical Physics Volume 18 (May, 2011), 621-624
$y_{n+2}=y_{n}+2(h) y_{n}^{\prime}+\frac{(2 h)^{2} y_{n}^{2}}{2!}+\frac{(2 h)^{3} y_{n}{ }^{3}}{3!}+\frac{(2 h)^{4} y_{n}{ }^{4}}{4!}+\frac{(2 h)^{5} y_{n}{ }^{5}}{5!}+\ldots O(h)^{6}$
Differentiating (18) and (19) once yields

$$
\begin{align*}
& y_{n+1}=y_{n}{ }^{(1)}+\frac{(h) y_{n}{ }^{2}}{2!}+\frac{(h)^{2} y_{n}{ }^{3}}{3!}+\frac{(h)^{3} y_{n}{ }^{4}}{4!}+\frac{(h)^{4} y_{n}{ }^{5}}{5!}+\ldots O(h)^{6}  \tag{20}\\
& y_{n+2}=y_{n}{ }^{(1)}+\frac{2(h) y_{n}{ }^{2}}{2!}+\frac{(2 h)^{2} y_{n}{ }^{3}}{3!}+\frac{(2 h)^{3} y_{n}{ }^{4}}{4!}+\frac{(2 h)^{4} y_{n}{ }^{5}}{5!}+\ldots O(h)^{6} \tag{21}
\end{align*}
$$

Equations $(18,19,20)$ are used for the evaluation of $y_{n+2}$ and $y_{n+2}^{\prime}$ respectively in the function $f_{n+1}=f\left(x_{n+2}, y_{n+2}, y_{n+1}^{\prime}\right)$ and $f_{n+2}=$ $f\left(x_{n+2}, y_{n+2}, y_{n+2}\right)$ step numbers will be adopting the lower step schemes, For example, the 4 -step method will adopt the 3 -step scheme as predictor for $\mathrm{y}_{\mathrm{n}+3}$ appearing in its equation.

## Numerical Experiment

The method developed or derived is applied to solve some sample problems of third order ordinary differential equations in order to test for its accuracy.
(1) $y^{\prime \prime \prime}=x-4 y^{\prime}, \quad y(0)=y^{\prime}(0)=0, y^{\prime \prime}(0)=1$

Theoretical solution: $\mathrm{y}(\mathrm{x})=(3 / 16)(1-\cos 2 \mathrm{x})+(1 / 8) \mathrm{x}^{2} ; \mathrm{h}=0.0025$
(2) $y^{\prime \prime \prime}=-y, \quad y(o)=0, y^{\prime}(0)=1, y^{\prime \prime}(0)=2$

Theoretical Solution: $y(x)=2(1-\cos x)+\sin x \quad h=0.0025$
(3) $y^{\prime \prime \prime}=-y y^{\prime \prime} y(o)=0, y^{\prime}(0)=0, y^{\prime \prime}(0)=1$

## Results

The absolute error (the comparative error analysis) obtained from the method (17) for $\mathrm{k}=3$ are compared with the continuous method for $\mathrm{k}=3$ in Awoyemi(2003) of the problem(1). The method is also used to solve various problems (that is 1-3). The results are as shown in the tables 1,2 and 3 below;

## Conclusion

A-three step discrete multistep method for general third order ordinary differential equations is developed. The method is of order five with principal error constant $\mathrm{C}_{\mathrm{p}+2}=0.00416667$.
Numerical results of the method are compared with the fifth-order continous method developed by [1].
An examination of Table 4 clearly reveals that the new method is more accurate than that of [1] for $\mathrm{k}=3$
